

Python Data Structures Cheat Sheet

List

Package/ Method	Description	Code Example
append()	The <code>`append()`</code> method is used to add an element to the end of a list.	Syntax: 1. 1 1. list_name.append(element)
		<div>Copied!</div>
		Example: 1. 1 2. 2 1. fruits = ["apple", "banana", "orange"] 2. fruits.append("mango") print(fruits)
		<div>Copied!</div>
copy()	The <code>`copy()`</code> method is used to create a shallow copy of a list.	Example 1: 1. 1 2. 2 3. 3 1. my_list = [1, 2, 3, 4, 5] 2. new_list = my_list.copy() print(new_list) 3. # Output: [1, 2, 3, 4, 5]
		<div>Copied!</div>
		Example: 1. 1 2. 2 3. 3 1. my_list = [1, 2, 2, 3, 4, 2, 5, 2] 2. count = my_list.count(2) print(count) 3. # Output: 4
		<div>Copied!</div>
Creating a list	A list is a built-in data type that represents an ordered and mutable collection of elements. Lists are	Example: 1. 1 1. fruits = ["apple", "banana", "orange", "mango"] <div>Copied!</div>

enclosed in square brackets [] and elements are separated by commas.

The `del` statement is

used to remove an element from

list. `del`

statement

removes the element at the specified index.

Example:

```
1. 1
2. 2
3. 3
```

```
1. my_list = [10, 20, 30, 40, 50]
2. del my_list[2] # Removes the element at index 2
3. print(my_list)
3. # Output: [10, 20, 40, 50]
```

Copied!

Syntax:

```
1. 1
```

The `extend()`

method is

used to add

multiple

elements to a

list. It takes an

iterable (such

as another list,

tuple, or

string) and

appends each

element of the

iterable to the

original list.

```
1. list_name.extend(iterable)
```

Copied!

Example:

```
1. 1
2. 2
3. 3
4. 4
```

```
1. fruits = ["apple", "banana", "orange"]
2. more_fruits = ["mango", "grape"]
3. fruits.extend(more_fruits)
4. print(fruits)
```

Copied!

Indexing in a

list allows you

to access

individual

elements by

their position.

In Python,

indexing starts

from 0 for the

first element

and goes up to

`length_of_list`

`- 1`.

Example:

```
1. 1
2. 2
3. 3
4. 4
5. 5
```

```
1. my_list = [10, 20, 30, 40, 50]
2. print(my_list[0])
3. # Output: 10 (accessing the first element)
4. print(my_list[-1])
5. # Output: 50 (accessing the last element using negative indexing)
```

Copied!

The `insert()`

method is

used to insert

an element.

Syntax:

```
1. 1
```

```
1. list_name.insert(index, element)
```

Copied!

Example:

```
1. 1
2. 2
3. 3
```

```
1. my_list = [1, 2, 3, 4, 5]
2. my_list.insert(2, 6)
3. print(my_list)
```

Copied!

Example:

You can use indexing to modify or assign new values to specific elements in the list.

```
1. 1
2. 2
3. 3
4. 4
```

```
1. my_list = [10, 20, 30, 40, 50]
2. my_list[1] = 25 # Modifying the second element
3. print(my_list)
4. # Output: [10, 25, 30, 40, 50]
```

Copied!

pop()

`pop()` method is another way to remove an element from a list in Python. It removes and returns the element at the specified index. If you don't provide an index to the `pop()` method, it will remove and return the last element of the list by default

Example 1:

```
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7
```

```
1. my_list = [10, 20, 30, 40, 50]
2. removed_element = my_list.pop(2) # Removes and returns the element
3. print(removed_element)
4. # Output: 30
5.
6. print(my_list)
7. # Output: [10, 20, 40, 50]
```

Copied!

Example 2:

```
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7
```

```
1. my_list = [10, 20, 30, 40, 50]
2. removed_element = my_list.pop() # Removes and returns the last elen
3. print(removed_element)
4. # Output: 50
5.
6. print(my_list)
7. # Output: [10, 20, 30, 40]
```

Copied!

Example:

To remove an element from a list. The `'remove()'` method removes the first occurrence of the specified value.

remove()

```
1. 1
2. 2
3. 3
4. 4
```

```
1. my_list = [10, 20, 30, 40, 50]
2. my_list.remove(30) # Removes the element 30
3. print(my_list)
4. # Output: [10, 20, 40, 50]
```

Copied!

Example 1:

The `'reverse()'` method is used to reverse the order of elements in a list

reverse()

```
1. 1
2. 2
3. 3
```

```
1. my_list = [1, 2, 3, 4, 5]
2. my_list.reverse() print(my_list)
3. # Output: [5, 4, 3, 2, 1]
```

Copied!

Slicing

You can use slicing to access a range of elements from a list.

Syntax:

```
1. 1
1. list_name[start:end:step]
```

Copied!

Example:

```
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7
8. 8
9. 9
10. 10
```

```
11. 11
12. 12

1. my_list = [1, 2, 3, 4, 5]
2. print(my_list[1:4])
3. # Output: [2, 3, 4] (elements from index 1 to 3)
4.
5. print(my_list[:3])
6. # Output: [1, 2, 3] (elements from the beginning up to index 2)
7.
8. print(my_list[2:])
9. # Output: [3, 4, 5] (elements from index 2 to the end)
10.
11. print(my_list[::-2])
12. # Output: [1, 3, 5] (every second element)
```

Copied!

Example 1:

```
1. 1
2. 2
3. 3
4. 4

1. my_list = [5, 2, 8, 1, 9]
2. my_list.sort()
3. print(my_list)
4. # Output: [1, 2, 5, 8, 9]
```

Copied!

Example 2:

```
1. 1
2. 2
3. 3
4. 4

1. my_list = [5, 2, 8, 1, 9]
2. my_list.sort(reverse=True)
3. print(my_list)
4. # Output: [9, 8, 5, 2, 1]
```

Copied!

Dictionary

Package/ Method	Description	Code Example
Accessing Values	You can access the values in a dictionary using their corresponding `keys`.	<p>Syntax:</p> <pre>1. 1 1. Value = dict_name["key_name"]</pre> <p>Example:</p> <pre>1. 1 2. 2 1. name = person["name"]</pre>

Copied!

```
2. age = person["age"]
```

Copied!

Syntax:

```
1. 1
```

Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.

```
1. dict_name[key] = value
```

Copied!

Example:

```
1. 1
2. 2
```

```
1. person["Country"] = "USA" # A new entry will be created.
2. person["city"] = "Chicago" # Update the existing value for the same
```

Copied!

The `clear()` method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.

Syntax:

```
1. 1
```

```
1. dict_name.clear()
```

Copied!

Example:

```
1. 1
```

```
1. grades.clear()
```

Copied!

Creates a shallow copy of the dictionary. The new dictionary contains the same key-value pairs as the original, but they remain distinct objects in memory.

Syntax:

```
1. 1
```

```
1. new_dict = dict_name.copy()
```

Copied!

Example:

```
1. 1
2. 2
```

```
1. new_person = person.copy()
2. new_person = dict(person) # another way to create a copy of diction
```

Copied!

Creating a Dictionary is a built-in data type that represents a collection of key-value

Example:

```
1. 1
2. 2
```

```
1. dict_name = {} #Creates an empty dictionary
2. person = { "name": "John", "age": 30, "city": "New York"}
```

pairs.
Dictionaries
are enclosed
in curly
braces `{}`.

Copied!

Syntax:

```
1. 1
```

Removes the
specified key-
value pair
from the
dictionary.

```
1. del dict_name[key]
```

Copied!

del

Raises a
'KeyError' if
the key does
not exist.

Example:

```
1. 1
```

```
1. del person["Country"]
```

Copied!

Syntax:

Retrieves all
key-value
pairs as tuples
and converts
them into a
list of tuples.
Each tuple
consists of a
key and its
corresponding
value.

```
1. 1
```

```
1. items_list = list(dict_name.items())
```

Copied!

items()

Example:

```
1. 1
```

```
1. info = list(person.items())
```

Copied!

You can
check for the
existence of a
key in a
dictionary
using the 'in'
keyword

Example:

```
1. 1
```

```
2. 2
```

```
1. if "name" in person:  
2.     print("Name exists in the dictionary.")
```

Copied!

key
existence

Syntax:

Retrieves all
keys from the
dictionary
and converts
them into a
list. Useful
for iterating
or processing
keys using
list methods.

```
1. 1
```

```
1. keys_list = list(dict_name.keys())
```

Copied!

keys()

Example:

```
1. 1
```

```
1. person_keys = list(person.keys())
```

Copied!

update()

The `'update()'` method merges the provided dictionary into the existing dictionary, adding or updating key-value pairs.

Syntax:

```
1. 1
1. dict_name.update({key: value})
```

Copied!

Example:

```
1. 1
1. person.update({"Profession": "Doctor"})
```

Copied!

values()

Extracts all values from the dictionary and converts them into a list. This list can be used for further processing or analysis.

Syntax:

```
1. 1
1. values_list = list(dict_name.values())
```

Copied!

Example:

```
1. 1
1. person_values = list(person.values())
```

Copied!

Sets

Package/ Method	Description	Code Example
		Syntax:
		<pre>1. 1 1. set_name.add(element)</pre>
add()	Elements can be added to a set using the <code>'add()'</code> method. Duplicates are automatically removed, as sets only store unique values.	<div>Copied!</div> <div>Example:</div> <pre>1. 1 1. fruits.add("mango")</pre> <div>Copied!</div>
clear()	The <code>'clear()'</code> method removes all elements from the set, resulting in an empty set. It updates the set in-place.	Syntax: <pre>1. 1 1. set_name.clear()</pre> <div>Copied!</div> <div>Example:</div> <pre>1. 1</pre>

```
1. fruits.clear()
```

Copied!

Syntax:

```
1. 1
```

```
1. new_set = set_name.copy()
```

copy()

The `copy()` method creates a shallow copy of the set. Any modifications to the copy won't affect the original set.

Copied!

Example:

```
1. 1
```

```
1. new_fruits = fruits.copy()
```

Copied!

Example:

Defining
Sets

A set is an unordered collection of unique elements. Sets are enclosed in curly braces `{}`. They are useful for storing distinct values and performing set operations.

```
1. 1  
2. 2
```

```
1. empty_set = set() #Creating an Empty Set  
2. fruits = {"apple", "banana", "orange"}
```

Copied!

Syntax:

```
1. 1
```

```
1. set_name.discard(element)
```

discard()

Use the `discard()` method to remove a specific element from the set. Ignores if the element is not found.

Copied!

Example:

```
1. 1
```

```
1. fruits.discard("apple")
```

Copied!

Syntax:

```
1. 1
```

```
1. is_subset = set1.issubset(set2)
```

issubset()

The `issubset()` method checks if the current set is a subset of another set. It returns True if all elements of the current set are present in the other set, otherwise False.

Copied!

Example:

```
1. 1
```

```
1. is_subset = fruits.issubset(colors)
```

Copied!

		<div>Syntax:</div> <div><pre>1. 1 1. is_superset = set1.issuperset(set2)</pre></div> <div>Copied!</div> <div>Example:</div> <div><pre>1. 1 1. is_superset = colors.issuperset(fruits)</pre></div> <div>Copied!</div>
issuperset()	<div>The <code>issuperset()</code> method checks if the current set is a superset of another set. It returns <code>True</code> if all elements of the other set are present in the current set, otherwise <code>False</code>.</div>	<div>Syntax:</div> <div><pre>1. 1 1. removed_element = set_name.pop()</pre></div> <div>Copied!</div> <div>Example:</div> <div><pre>1. 1 1. removed_fruit = fruits.pop()</pre></div> <div>Copied!</div>
pop()	<div>The <code>pop()</code> method removes and returns an arbitrary element from the set. It raises a <code>KeyError</code> if the set is empty. Use this method to remove elements when the order doesn't matter.</div>	<div>Syntax:</div> <div><pre>1. 1 1. set_name.remove(element)</pre></div> <div>Copied!</div> <div>Example:</div> <div><pre>1. 1 1. fruits.remove("banana")</pre></div> <div>Copied!</div>
remove()	<div>Use the <code>remove()</code> method to remove a specific element from the set. Raises a <code>KeyError</code> if the element is not found.</div>	<div>Syntax:</div> <div><pre>1. 1 1. 2 2. 2 3. 3 4. 4 1. union_set = set1.union(set2) 2. intersection_set = set1.intersection(set2) 3. difference_set = set1.difference(set2) 4. sym_diff_set = set1.symmetric_difference(set2)</pre></div> <div>Copied!</div> <div>Example:</div>
Set Operations	<div>Perform various operations on sets: <code>'union'</code>, <code>'intersection'</code>, <code>'difference'</code>, <code>'symmetric difference'</code>.</div>	

```
1. 1
2. 2
3. 3
4. 4
```

```
1. combined = fruits.union(colors)
2. common = fruits.intersection(colors)
3. unique_to_fruits = fruits.difference(colors)
4. sym_diff = fruits.symmetric_difference(colors)
```

Copied!

Syntax:

```
1. 1
```

```
1. set_name.update(iterable)
```

Copied!

Example:

```
1. 1
```

```
1. fruits.update(["kiwi", "grape"])
```

Copied!
